

How **Skipily**, the **provider's shop** and **Sendcloud** work together: Skipily is the marketplace where customers order from the provider. Sendcloud is the shipping platform the provider uses to create labels and handle shipping. Both are connected through the provider portal.

1 · Setting up the connection (one-time)

- 1 The provider signs in to their **own Sendcloud account** and creates a **Public Key** and **Secret Key** under *Settings → Integrations → Sendcloud API*.
- 2 In the provider portal under **Master data → Sendcloud shipping**, they paste both keys and click "Connect Sendcloud".
- 3 Skipily validates the keys **live against the Sendcloud API**, reads the account name and stores the credentials **encrypted and server-side only**. The Secret Key never reaches the browser or app users.

2 · The shipping process per order

- 1 A customer orders a provider's product in the **Skipily shop** (app or web).
- 2 Payment runs via Stripe; the order appears in **Provider portal → Orders**.
- 3 The provider picks and packs the goods.
- 4 Using **Sendcloud**, they create and print the shipping label and choose the carrier (DHL, DPD, UPS, GLS, PostNL and many more).
- 5 The **tracking number** and **tracking link** are stored on the order; the status changes to "shipped".
- 6 The customer receives **tracking** (Track & Trace).
- 7 Returns are handled via the **Sendcloud returns portal** when needed.

3 · Live today vs. planned automation

Live today

- Connecting the Sendcloud account via API key (Public/Secret).
- Entering tracking number & link in the provider portal; status "shipped".
- Tracking for customers.

Planned next step

- **Automatic order sync**: a Skipily order automatically creates the Sendcloud shipment incl. label.
- Tracking number and link flow back to the order **automatically** – no manual entry.

4 · Security & roles

- Only the **business owner or admins** can change the Sendcloud connection.
- The **Secret Key** is processed only in a server-side function and never delivered.
- Access control at the database level (Row Level Security); anonymous access is fully blocked.
